Deployed website: <https://RautelaAbhishek.github.io>

GitHub repository: <https://github.com/RautelaAbhishek/RautelaAbhishek.github.io>

Overview

This project is a professional profile website deployed on GitHub Pages. In the portfolio, I included APIs, JavaScript libraries and some basic JavaScript features as well as a page tracker. I used JQuery and Bootstrap and put JavaScript files in a separate file and worked with cookies to allow the page to tell if it is the first visit of the user and when their last visit was.

General Requirements

Professional Profile Website

I created a personal website in `index.html`. The page includes my name, headshot, email contact feature, background summary, education, experience, and skills. I then deployed it on GitHub using GitHub actions

WAPH Course Page

I created a separate course page, `waph.html` and added the basic course info as well as a link to it in the `index.html` page.

Non-technical Requirements

Bootstrap Framework

I included a bootstrap CDN script into the main `index.html` and used that for styling the page.

Page Tracker

I included a Flag Counter page tracker near the bottom of the homepage. by going to the link and copying over the tag using my selected options

Technical Requirements

jQuery and JavaScript Library

The project uses JQuery as well as Day.js and clock.js from the waph-phung github. The scripts were added in the body tag of `index.html`

Digital Clock

I added a script to get an updating datetime in `script.js` using Day.js that updates every 500ms.

Analog Clock

I used the `clock.js` script from the course resources as well as the canvas tag to display the analog clock in the `index.html` page.

Show/Hide Email

I added a function in `email.js` that checks to see if email is shown when the user clicks on the button. Then, it toggles whether the email is shown or not.

Extra JavaScript Functionality

For the extra JavaScript functionality, I added a button that changes the background to a random color when clicked. This is not persistent so when the user refreshes the page it goes back to the default color. I did this by generating 6 different hex digits and combining them to get a hex color and then applying that to the background-color.

Public Web API Integrations

Disclaimer

I included a disclaimer to reduce any legal issues I may encounter from using the public APIs.

JokeAPI

I integrated JokeAPI using the required **Any** category endpoint as mentioned:

```
https://v2.jokeapi.dev/joke/Any?  
blacklistFlags=nsfw,religious,political,racist,sexist,explicit
```

I noticed that some jokes had a setup and delivery as well so I added a check for it and made the delivery have a line break inbetween the setup and delivery for better readability.

The page loads a joke when it loads or every 60 seconds.

Cat Image API

I integrated The Cat API to display a random cat image:

```
https://api.thecatapi.com/v1/images/search
```

This loads an image of a cat when the page loads or when the user clicks the generate new image button.

JavaScript Cookies

I implemented cookies to remember returning visitors. On a first visit, the site displays:

```
Welcome to my homepage for the first time!
```

and on later visits it displays:

```
Welcome back! Your last visit was <the date/time of last visit>
```

The cookie value is updated every time the visitor loads the page.

Conclusion

This project helped me practice creating a complete front-end website with HTML, Bootstrap, JavaScript, jQuery, Day.js, cookies, and public API integration. I also got some experience in deploying onto GitHub Pages.
